Dear Parents of Rising Sixth Grade Students:

The 2007 Virginia General Assembly passed a law that requires the Virginia Department of Health to provide the parents of rising sixth grade girls with information on Human Papillomavirus (HPV) and the Human Papillomavirus Vaccine to ensure that parents are well informed of the Centers for Disease Control and Prevention (CDC) recommendation that girls 11-12 years old receive the vaccine. In 2011, the CDC made an additional recommendation that boys of the same age also routinely receive HPV vaccine.

Some strains of HPV cause cervical cancer in women. HPV is also associated with several less common cancers in both men and women. The HPV vaccine is the first vaccine developed to prevent most cervical cancers. The vaccine targets the strains of HPV that most commonly cause cervical cancer and is highly effective in preventing infection with these types of HPV in young people who have not been exposed to them before getting the vaccine.

After reviewing the information provided on the reverse side of this letter, please contact your health care provider to determine if your child should receive the vaccine series. HPV vaccine is available from your doctor, military clinics, or the local health department. If you choose to have your child vaccinated, you may provide documentation to your child's school and they will update your child's school immunization record.

Should you have additional questions, please contact Tira Hanrahan, Division of Immunization, Virginia Department of Health, by telephone at 804-864-8055 or by email at tira.hanrahan@vdh.virginia.gov or the School Health Nurse Specialist, Office of Student Services, Virginia Department of Education, by telephone at 804-786-5703.

Sincerely,

A handwritten signature in blue ink that reads "Marissa J. Levine".

Marissa J. Levine, MD, MPH, FAAFP
State Health Commissioner

Facts for Parents about HPV and the HPV Vaccine*

What is human papillomavirus (HPV)?

HPV is a common virus that is spread through sexual contact. Most of the time, HPV has no symptoms so people do not know they have it. There are many different types of HPV. In most people, HPV goes away on its own within two years and does not cause health problems. Sometimes, HPV infections will persist and can cause health problems. Experts do not know why HPV goes away in some cases, but not in others.

How common is HPV?

HPV is very common. About 14 million people in the U.S., including teens, get newly infected each year.

Does HPV cause cancer?

HPV causes most cervical cancer in women and several other types of cancers in both men and women. Other types of HPV can cause genital warts in both males and females.

How common are cancers caused by HPV?

Worldwide, cervical cancer is the fourth most frequent cancer in women. In the U.S., about 12,000 women get cervical cancer every year and about 4,000 are expected to die from it. Every year, about 17,500 women and 9,300 men are affected by cancers caused by HPV.

What is the HPV vaccine?

The HPV vaccine is the first vaccine developed to prevent most cervical cancers and genital warts. It works by protecting against the types of HPV that most commonly cause these conditions.

Two doses of vaccine are required if the first dose is given before 15 years of age; three doses are required if the first dose is given later.

For more information, ask your child's healthcare provider or call 800-CDC-INFO (800-232-4636)
Website:

<http://www.cdc.gov/vaccines/who/teens/index.html>

Who should get the HPV vaccine?

Doctors recommend this vaccine for all 11-12 year old girls and boys. The vaccine offers the best protection to preteens who receive all doses and have time to develop an immune response before ever being exposed to the virus. Also, HPV vaccine produces a higher immune response in preteens than older adolescents.

Is the HPV vaccine effective?

The HPV vaccine works extremely well. The amount of HPV infections in teen girls decreased by 56% in the four years after the vaccine was recommended in 2006. Research has also shown that fewer teens are getting genital warts since the vaccine has been in use. In other countries, research shows that HPV vaccine has already decreased the amount of pre-cancer in women. The vaccine works for at least 10 years, and probably longer, without becoming less effective.

Is the HPV vaccine safe?

The HPV vaccines have been used in the U.S. and around the world for several years and have been very safe. Several mild to moderate problems are known to occur. They include pain, redness, or swelling in the arm where the shot is given, and sometimes fever, nausea or headache. Serious side effects are rare.

Brief fainting spells and related symptoms (such as jerking movements) can happen after any medical procedure, including vaccination. Sitting or lying down for about 15 minutes after a vaccination can help prevent fainting and injuries caused by falls.
