1.0 INTRODUCTION

McCabe Environmental Services, L.L.C. (McCabe) was retained by Lyndhurst Board of Education (Client) to conduct lead in drinking water testing at Lyndhurst High School located at 400 Weart Avenue, Lyndhurst, New Jersey 07071.

The project information is as follows:

<u>Client Name</u> : <u>Contact Person</u> :	Lyndhurst Board of Education Mr. Keith Matino
Project Name:	Lyndhurst Public Schools –
Project Location:	Lyndhurst High School Lead in Drinking Water Testing 400 Weart Avenue Lyndhurst, New Jersey 07071
Date(s) of Service:	April 20, 2022
McCabe Personnel:	Gary Clare

2.0 <u>SCOPE OF WORK</u>

Drinking water testing was performed at Lyndhurst High School located at 400 Weart Avenue, Lyndhurst, New Jersey 07071 on April 20, 2022. The purpose of the testing was to determine if the building's plumbing was having an adverse impact on water quality, specifically with regard to lead concentrations. Samples were collected from various potential drinking water outlets located throughout the building. Of the thirteen (13) samples collected, the **Basement Slop Sink** was found to exceed the EPA Lead and Copper Rule Maximum Contaminant Level (MCL) of 15 parts per billion and also the EPA Lead in Drinking Water at Schools and Child Care Facilities standard of 20 ppb.

3.0 **PROCEDURES**

After determining which outlets would be sampled, McCabe personnel collected a "first draw" sample at each location. A "first draw" is the initial water that is first to come out of the tap after a period of inactivity. Following the "first draw", a "30 second flush" sample was also collected where the main service line comes into the building. An additional 3-minute flush sample was collected where the main service line comes into the building as well. All samples were collected into 250 mL sterile bottles, labeled with a sample identification, and analyzed in accordance with EPA approved methods to determine the level of lead in drinking water. Samples were analyzed by an accredited laboratory.

The U.S. Environmental Protection Agency (EPA) has established National Primary Drinking Water Regulations (NPDWR) that set mandatory water quality standards for drinking water contaminants. These are enforceable standards called "maximum contaminant levels" or "MCL", which are established to protect the public against consumption of drinking water contaminants that present a risk to human health. An MCL is the maximum allowable amount of a contaminant in drinking water which is delivered to the consumer.

The EPA has established the Lead and Copper Rule that sets standards for state and public water systems. This rule has set an MCL for lead at 15 parts per billion (ppb) for a one liter sample. However, the EPA also established the

Lead in Drinking Water at Schools and Child Care Facilities in which the EPA recommends an MCL of 20 ppb for a 250 milliliter first draw sample. In order to be more stringent, for our report purposes we have compared all results to both the 15 ppb and the 20 ppb standards.

4.0 <u>TABLE OF SAMPLE RESULTS</u>

The following table presents all sample results in order of sample identification:

Sample ID	Sample Location	Lead Result	Exceeds (MCL 15 ppb)	Exceeds (MCL 20 ppb)
01	Basement Slop Sink – POE – First Draw	832	X	Х
02	Basement Slop Sink – POE – 30 Second Flush	5.0	Pass	Pass
03	Basement Slop Sink – POE – 3 Minute Flush	0.7	Pass	Pass
04	1 st Floor Water Cooler Outside of Room 149	< 0.5	Pass	Pass
05	Cafeteria – Left Sink	< 0.5	Pass	Pass
06	Cafeteria – Middle Sink	< 0.5	Pass	Pass
07	Cafeteria – Right Sink	< 0.5	Pass	Pass
08	Water Fountain Near Girls Locker Room	< 0.5	Pass	Pass
09	Water Fountain Near Room 104B	< 0.5	Pass	Pass
10	2 nd Floor Water Fountain Near Room 200	< 0.5	Pass	Pass
11	Library Sink	6.3	Pass	Pass
12	Nurse's Office Sink – Left – 120A	< 0.5	Pass	Pass
13	Nurse's Office Sink – Right – 120C	< 0.5	Pass	Pass

McCabe Environmental Services, L.L.C.

Client: Lyndhurst BOE – Lyndhurst High School Lead in Drinking Water Testing Report

5.0 DISCUSSION AND CONCLUSION

A total of thirteen (13) were collected from Lyndhurst High School. One sample, the **Basement Slop Sink**, was found to be greater than the EPA Lead and Copper Rule standard of 15 ppb and also greater than the EPA Lead in Drinking Water at Schools and Child Care Facilities standard of 20 ppb. All other samples were found to be less than the EPA standards of 20 ppb and 15 ppb.

Only the nearest point of entry first draw sample located at the basement slop sink had a concentration exceeding the regulatory standards for lead as established by the EPA with a concentration of 832 ppb. Further sampling of the nearest point of entry illustrates a significant decrease in lead concentrations. The 30 second flush sample of the basement slop sink passed regulatory standards set for lead by the EPA with a concentration of 5 ppb. Additionally, the 3-minute flush sample of the basement slop sink passed the regulatory standards set for lead by the EPA with a concentration of 0.7 ppb. Often, "first draw" samples have higher concentrations because compounds leach from the surrounding pipe as water sits stagnant for a duration of time. The lead concentration found at this location indicate that there are potentially lead pipes within the faucet and/or immediate fittings and soldered elbows.

McCabe recommends if the basement slop sink were to be used for water consumption, the outlet should be flushed for at least thirty seconds in order to achieve lead concentrations below regulatory standards set by the EPA.

In addition, McCabe Environmental recommends annual drinking water sampling to ensure that the building's plumbing is not having an adverse impact on water quality.

This laboratory is in compliance with the NELAC requirements of procedures used except where indicated.

This report contains results for the parameters tested, under the sampling conditions described on the Chain Of Custody, as received by the laboratory. This report is incomplete unless all pages indicated in the pagination at the bottom of the page are included.

A scanned version of the COC form accompanies the analytical report and is an exact duplicate of the original.

If you are the client above and have any questions concerning this testing, please do not hesitate to contact Phoenix Client Services at ext.200. The contents of this report cannot be discussed with anyone other than the client listed above without their written consent.

Sincerely yours,

XI:lle

Phyllis/Shiller Laboratory Director

Attachment B.i: Plumbing Profile Instructions

Plumbing Profile Questions	What Your Answers to the Plumbing Profile Questions Mean
The questions in this column will help you determine whether lead is likely to be a problem in your facility, and will enable you to prioritize your sampling effort.	This column discusses the significance of possible answers to the plumbing profile questions.
Background Information	
	Older Buildings – Through the early 1900s, lead pipes were commonly used for interior plumbing in certain parts of the country in public buildings and private homes. Plumbing installed before 1930 is more likely to contain lead than newer pipes. Between 1920 and 1950 galvanized pipes were also used for plumbing. After 1930, copper generally replaced lead as the most commonly used material for water pipes. Up until the mid- to late-1980s (until the lead-free requirements of the 1986 Safe Drinking Water Act Amendments took effect), lead solder was typically used to join these copper pipes. The efforts of your public water supplier over the years to minimize the corrosiveness of the water may have resulted in mineral deposits forming a coating on the inside of the water pipes (passivation). This coating insulates the water from the plumbing and results in decreased lead levels in water. If the coating does not exist or is disturbed, the water is in direct contact with any lead in the plumbing system.

	Newer Buildings – New buildings are not likely to have lead pipes in their plumbing systems, but they are very likely to have copper pipes with solder joints. Buildings constructed prior to the late 1980s, before the lead-free requirements of the 1986 Safe Drinking Water Act Amendments, may have joints made of lead solder. Buildings constructed after this period should have joints made of lead-free solders. Even if "lead-free" materials were used in new construction and/or plumbing repairs, lead leaching may occur.
2. If built or repaired after 1986, were lead-free plumbing and solder used in accordance with the lead-free requirements of the 1986 Safe Drinking Water Act Amendments? What type of solder has been used?	The 1986 Amendments to the Safe Drinking Water Act banned plumbing components that contained elevated levels of lead. Lead-free solder and flux (not more than 0.2% lead) and pipe, pipe fittings, and fixtures (not more than 8% lead) must now be used. The leaching potential of lead-free (i.e., tin- antimony) solder is much less than lead solder. The leaching potential of lead-free pipe, pipe fittings, and fixtures is also less, but leaching is still possible.
Was lead solder used in your plumbing system? Note the locations of lead solder.	If lead-free materials were not used in new construction and/or plumbing repairs, elevated lead levels can be produced. If the film resulting from passivation does not exist or has not yet adequately formed, any lead that is present is in direct contact with the water.
	In some areas of the country, it is possible that high-lead materials were used until 1988 or perhaps even later. Your local plumbing code authority or building inspector may be able to provide guidance regarding when high-lead materials were last used on a regular basis in your area.
3. When were the most recent plumbing repairs and replacements made (note locations)?	Corrosion occurs (1) as a reaction between the water and the pipes and (2) as a reaction between the copper and solder (metal-to-metal). This latter reaction is known as galvanic corrosion, which can be vigorous in new piping. If lead solders were used in the piping or if brass faucets, valves, and fittings containing alloys of lead were installed <i>(see response to Walk Through Question 5 below for further discussion of brass)</i> , lead levels in the water may be high. After about 5 years, however, this type of reaction (galvanic corrosion) slows down and lead gets into water mainly as a result of water being corrosive. If the water is non- corrosive, passivation is likely to have occurred and to have reduced opportunities for lead to get into the water system.
	For these reasons, if the building (or an addition, new plumbing, or repair) is less than 5 years old and lead solder or other materials (e.g., brass faucets containing lead alloys) were used, you may have elevated lead levels. If water supplied to the building is corrosive, lead can remain a problem regardless of the plumbing's age.
4. With what materials is the service connection (the pipe that carries water to the school from the public water system's main in the street) made? Note the location where the service connection enters the building and connects to the interior plumbing. (This is the POE location)	Lead piping was often used for the service connections that join buildings to public water systems. The service connection is the pipe that carries drinking water from a public water main to a building. Some localities actually required the use of lead service connections up until the lead-free requirements of the 1986 Safe Drinking Water Act Amendments took effect. Although a protective layering of minerals may have formed on these pipes, vibrations can cause flaking of any protective build-up and, allowing lead contamination to occur.
5. Is there point of entry (POE) or point of use (POU) treatment in use?	Are there water treatment units in your plumbing system? Treatment units could be, but are not limited to, ion exchange units, filter cartridge, reserve osmosis, etc.
6. Do you have tanks in your plumbing system (pressure tanks, gravity storage tanks)?Note the location of any tanks, and any available	Some older tanks may contain coatings that are high in lead content. Tanks may accumulate sediment that could be flushed back into the plumbing system under certain circumstances. You may wish to contact the supplier or manufacturer to obtain
information about the tank; e.g., manufacturer, date of installation.	information about coatings. You may also wish to hire a plumber or tank service contractor to inspect your tanks, especially gravity storage tanks that are located outside of the building.
7. Does the school have a filter maintenance and operation program? If so, who is responsible for this program? What is the process for adding filters?	A program for the maintenance and the upkeep of filters on drinking water outlets is necessary to ensure the effectiveness of the filters. Most filters recommend replacement after six months. If the filters need replacement every six months, the program will include a procedure for ensuring that every six month old filter is replaced. An individual should be responsible for ensuring that this filter maintenance program is followed.
	If the school would like to add a filter to a water outlet, what is the process? Does a request form have to be completed and submitted to the individual in charge of maintenance? Do all filters need to be added at a certain time of year to follow the maintenance program?
 Bo outlets that provide drinking water have accessible screens or aerators? (Standard faucets usually have screens. Many coolers and bubblers also have screens.) Note the locations. Have these screens been cleaned? Note the locations. 	Lead-containing sediments that are trapped on screens can be a significant source of lead contamination. Sediments should be tested for the presence of lead, and your facility should create a routine maintenance program to clean the screens frequently. If sediment has been a reoccurring problem regular cleaning of the screens and additional investigating into why the debris is accumulating is appropriate. However, the manufacturer or water service provider should be contacted to obtain instructions.
9. Have there been any complaints about water taste (metallic, etc.) or rusty appearance? Note the locations.	Although you cannot see, taste, or smell lead dissolved in water, the presence of a metallic taste or rusty appearance may indicate corrosion and possible lead contamination.

 ing files to determine whether aples have been taken from your or any contaminants (also check with ablic water supplier). Name of contaminant(s)? What concentrations of these contaminants were found? What was the pH level of the water? Is testing done regularly at your facility? 	Lead testing may have previously been done voluntarily under the Lead Contamination Control Act. Results of analyses of general water quality, such as measures of pH, calcium hardness, and carbonate alkalinity, can provide important clues about the corrosiveness of the water. Generally, the higher the values of these parameters, the less likely it is that your water is corrosive. If you have no data from your school, your public water system should at least be able to provide information about the general water quality.
11. Other plumbing questions:	You should incompare this is for a first in the
 Are blueprints of the building available? Are there known plumbing "dead• ends," low use areas, existing leaks or other "problem areas"? Are renovations being planned for part or all of the plumbing system? 	
Walk-Through	
1. Confirm the material that the service line is made of visually	See Background Information Question #4.
2. Confirm the presence of POE or POU	See Background Information Question #5
treatment.	
3. Specifically, what are the potable water pipes made of in your facility (note the locations)?	Survey your building for exposed pipes, preferably accompanied by an experienced plumber who should be able to readily identify the composition of pipes on site. Most buildings have a combination of different plumbing materials:
• Lead	• Lead nines are dull gray in color and may be set it.
Plastic	• Lead pipes are dull gray in color and may be easily scratched by an object such as a knife or
 Galvanized Metal 	key. Lead pipes are a major source of lead contamination in drinking water.
Cast Iron	• Galvanized metal nines are grav or silver grav in set
• Copper	• Galvanized metal pipes are gray or silver-gray in color and are usually fitted together with threaded joints. In some instances, as we have a set of the
• Other	threaded joints. In some instances, compounds containing lead have been used to seal the threads joining the pipes. Debris from this material, which has fallen inside the pipes, may be a source of contamination.
Note the location of the different types of pipe, if applicable, and the direction of water flow through the building. Note the areas of the building that receive water first, and which areas receive water last.	 Copper pipes are red-brown in color. Corroded portions may show green deposits. Copper pipe joints were typically joined together with lead solders until the lead-free requirements of the 1986 Safe Drinking Water Act Amendments took effect. Plastic pipes, especially those manufactured abroad, may contain lead. If plastic pipes are used, be sure they meet NSF International standards. (Note: NSF International is an independent, third-party testing organization. Product listings can be obtained by wisiting their Web site of the product of the product listings can be obtained by
4. Is any electrical equipment grounded to	visiting their Web site at <u>http://www.nsf.org/ business/search_listings/index/asp.</u>
water pipes? Note the locations.	I electrical equipment, such as telephones, has been installed using water pipes as a ground, the lectric current traveling through the ground wire will accelerate the corrosion of any interior lumbing containing lead. The practice should be avoided, if possible. However, if existing vires are already grounded to water pipes, the wires <i>should not be removed</i> from the pipes nless a qualified electrician installs an alternative grounding system. Check with your local uilding inspector on this matter. Your state or local building code may require grounding of ne wires to the water pipes. Improper grounding of electrical equipment may cause severe hock.
faucets are brass on the inside.)	brass fittings, faucets, and valves are golden yellow in color, similar to copper in appearance, or replated with chrome. Brass is composed primarily of two metals, copper and zinc. Most rasses contain lead ranging from 2 percent to 8 percent. That lead can contaminate the water
You may want to note the locations on a map or diagram of your facility and make extensive notes that would facilitate future analysis of lead sample results. The performance of the second second second second second second statement of the second secon	Ander Surface which it is sineared on the machined surfaces during production. After 1996, brass trings installed in drinking water outlets such as faucets and water coolers must meet NSF andards for lead content. While this percentage is considered lead-free under the 1986 Safe rinking Water Act Amendments, some contamination problems still may occur. Older brass ucets may contain higher percentages of lead and lead solder in their interior construction and use contamination problems. Note that your state or local government may have imposed this andard prior to 1988.
le: an In	ed to develop the product. A study revealed that fabricated faucets tend to contribute less ad to the water than faucets manufactured by the permanent mold process, regardless of the nount of lead in the alloy. response to a requirement of the 1996 SDWA, EPA worked with the plumbing industry and SF International to develop a voluntary industry standard that is designed to minimize the

1

	amounts of lead being leached from these products. This standard is NSF/ANSI Standard 61, Section 9. Since 1998, all plumbing fixtures for use as drinking water supply must meet this standard. You should require NSF/ANSI 61 certification on all drinking water system products purchased. Include a copy of the NSF/ANSI 61 certificate as a requirement on your purchase orders. The distributor or manufacturer can provide you with a list of certified products. You should require NSF/ANSI 61 certification on all drinking water system products used in new construction and inform your architects and revise your building specifications.
 6. How many of the following outlets provide water for consumption? Note the locations. Water Coolers Bubblers Ice Makers Kitchen Taps Drinking Fountains or Taps 	In addition to lead components in the plumbing system, lead solders or lead in the brass fittings and valves used in some taps, bubblers, and refrigerated water coolers may be sources of lead. It is important to identify the locations of all such drinking water outlets. Faucets in restrooms should not be used to obtain water for drinking. Although they may be adequate for washing hands, they may not be appropriate for drinking purposes. You may consider posting "do not drink" signs.
7. Has your school checked the brands and models of water coolers and compared them to the list of recalled water coolers in Appendix H.i Note the locations of any recalled coolers.	Water coolers may be a major source of lead contamination. The Federal Consumer Product Safety Commission negotiated an agreement with Halsey Taylor through a consent order agreement published in June 1990 to provide a replacement or refund program that addresses all the water coolers listed by EPA as having lead-lined tanks. Halsey Taylor was the only company identified by EPA as manufacturing some water coolers with lead-lined tanks. Additionally, some coolers manufactured by EBCO had a bubbler valve and one soldered joint that contained lead. See Attachment H.i of this document for a summary of EPA's list of water coolers found to contain lead. Use the list to beln prioriting sume water of the taylor water coolers found to
	having a lead-lined tank, you should not use the water for drinking, and you should remove the cooler immediately as these coolers pose the highest risk of contamination
dishes or laundry? Note the locations.	requent leaks, rust-colored water, and stains on fixtures, dishes, and laundry are signs of corrosive water. Blue-green deposits on pipes and sinks indicate copper corrosion; brown stains result from the corrosion of iron. Where such signs occur, high levels of lead, copper, and iron may be present in the water. Lead can accumulate with iron, which can form sediments that are hard to remove.
Permanently? Temporarily?	Permanently out of service water outlets are outlets that are no longer being used and the facility plans to decommission in the future.
	Temporarily out of service water outlets are outlets that require repair or replacement and will be put back in service once they are operational.

Attachment F - Pre - Sampling Water Use Certification

TO BE COMPLETED BY THE LYNDHURST BOE DISTRICT REPRESENTATIVE:							
School Name:	Lyndhurst High School						
Sample collection address:	400 Weart Avenue Lyndhurst, New Jersey 07071						
Water was last used:	Time: 3:00pm	Date:04/19/22					
Sample commencement:	Time:9:00am	Date:04/20/22					
I have read the Lead Drinking Water Testing Sampling Plan and Quality Assurance Project Plan and I am certifying that samples were collected in accordance with these plans.
