Lead Testing of School Drinking Water

07/08/2026

Safe and healthy school environments can foster healthy and successful children. To protect public health, the Public Health Law and New York State Health Department (NYSDOH) regulations require that all public schools and boards of cooperative educational services (BOCES) test lead levels in water from every outlet that is being used, or could potentially be used, for drinking or cooking. If lead is found at any water outlet at levels above 5 parts per billion (ppb), the NYSDOH requires that the school take action to reduce the exposure to lead.

What is first draw testing of school drinking water for lead?

The “on-again, off-again” nature of water use at most schools can raise lead levels in school drinking water. Water that remains in pipes overnight, over a weekend, or over vacation periods stays in contact with lead pipes or lead solder and, as a result, could contain higher levels of lead. This is why schools are required to collect a sample after the water has been sitting in the plumbing system for a certain period of time. This “first draw” sample is likely to show higher levels of lead for that outlet than what you would see if you sampled after using the water continuously. However, even if the first draw sample does not reflect what you would see with continuous usage, it is still important because it can identify outlets that have elevated lead levels.

Which samples exceeded 5 ppb during the first draw testing?

Alice E. Grady Elementary School – Elmsford Union Free School District				
Date	Sample ID	Floor	Location	Lead Level (ppb)
06/16/2026	AEG-1	Basement	Room 111 - Sink	5.43
06/16/2026	AEG-2	Basement	Room 113 - Sink	7.42
06/16/2026	AEG-3	Basement	Room 115 - Sink	8.90
06/16/2026	AEG-4	Basement	Room 117 - Sink	8.04
06/16/2026	AEG-11	Basement	Room 133 - Sink	8.04
06/16/2026	AEG-12	Basement	Room 135 - Sink	15.1
06/16/2026	AEG-18	First	Kitchen – Food Prep Sink	6.94
06/16/2026	AEG-19	First	Room 211 - Sink	6.97
06/16/2026	AEG-23	First	Room 233 - Sink	5.02
06/16/2026	AEG-24	First	Room 234 - Sink	13.5

What is the initial response to results that exceed 5 ppb?

Outlets with lead levels above the action level (5 ppb) are immediately removed from service, unless the outlet is a sink faucet needed for handwashing. In that case, a sign is posted at the outlet indicating that the sink is not to be used as a potable water source. Faculty using these

specific outlets are informed of the results and the new usage parameters of the outlets. Outlets that test below the action level remain in service with no restrictions.

Specific Response Actions

Alice E. Grady Elementary School – Elmsford Union Free School District	
Location	Response Action
Room 111 - Sink	Add signage, hand washing only
Room 113 - Sink	Add signage, hand washing only
Room 115 - Sink	Add signage, hand washing only
Room 117 - Sink	Add signage, hand washing only
Room 133 - Sink	Add signage, hand washing only
Room 135 - Sink	Add signage, hand washing only
Kitchen – Food Prep Sink	Add signage, hand washing only
Room 211 - Sink	Add signage, hand washing only
Room 233 - Sink	Add signage, hand washing only
Room 234 - Sink	Add signage, hand washing only

Should the District wish to perform remediation to reintroduce outlets as potable water sources without restrictions, actions may include replacing the fixture or outlet, installing point of use filters, replacing plumbing, or creating a standard flushing program. Post remediation water testing will be performed to confirm the response action has achieved its intended purpose and returned lead in water levels to at, or below, the 5.0 ppb limit before the outlet is put back into use as a potable water source.

What are the health effects of lead?

Lead is a metal that can harm children and adults when it gets into their bodies. Lead is a known neurotoxin, particularly harmful to the developing brain and nervous system of children under 6 years old. Lead can harm a young child's growth, behavior, and ability to learn. Lead exposure during pregnancy may contribute to low birth weight and developmental delays in infants. There are many sources of lead exposure in the environment, and it is important to reduce all lead exposures as much as possible. Water testing helps identify and correct possible sources of lead that contribute to exposure from drinking water.

What are the other sources of lead exposure?

Lead is a metal that has been used for centuries for many purposes, resulting in widespread distribution in the environment. Major sources of lead exposure include lead-based paint in older housing, and lead that built up over decades in soil and dust due to historical use of lead in gasoline, paint, and manufacturing. Lead can also be found in a number of consumer products, including certain types of pottery, pewter, brass fixtures, foods, plumbing materials, and cosmetics. Lead seldom occurs naturally in water supplies but drinking water could become a possible source of lead exposure if the building's plumbing contains lead. The

primary source of lead exposure for most children with elevated blood-lead levels is lead-based paint.

Should your child be tested for lead?

The risk to an individual child from past exposure to elevated lead in drinking water depends on many factors; for example, a child's age, weight, amount of water consumed, and the amount of lead in the water. Children may also be exposed to other significant sources of lead including paint, soil and dust. Since blood lead testing is the only way to determine a child's blood lead level, parents should discuss their child's health history with their child's physician to determine if blood lead testing is appropriate. Pregnant women or women of childbearing age should also consider discussing this matter with their physician.
